About This Designer’s Guide

Agilent Technologies optocouplers can be used in an array of isolation applications ranging from power supply and motor control circuits to data communication and digital logic interface circuits.

To help you choose and design with Agilent Technologies isolation components, this Designer’s Guide contains popular application circuits and recommended Agilent optocouplers.

This handbook begins with a selection guide followed by sections discussing critical optocoupler design parameters such as Insulation and Withstand Voltage, Regulatory Agency Safety Standards, Common-Mode Transient Rejection, Product Life and light emitting diode (LED) aging. The rest of the guide consists of application circuits.

Each application circuit is accompanied by:
1. A brief description.
3. Circuit benefits.
4. A list of alternative Agilent parts indicating comparably performing products available in varying package styles for maximum design flexibility.

Data sheets for products recommended in this guide can be found on the Agilent Technologies’ web site at www.agilent.com/semiconductors, or they may be ordered from your local Agilent representative.

How to Use This Guide
Several indexes are included to help locate applications and products.
• The table of contents lists all the applications by their general description.
• Selection Guides in the form of tables contain basic product specifications which allow you to quickly select the products most suitable for your applications.

How to Order
To order any component in this guide or additional applications information, call your authorized Agilent distributor nearest you.

Although product information and illustrations in this guide were current at the time it was approved for printing, Agilent Technologies, in a continuing effort to offer excellent products at a fair value, reserves the right to change specifications, designs, and models without notice.
## Table of Contents

**Optocoupler Selection Guide** ................................................................. 1
  - 15 MBd Logic Gate Optocoupler .......................................................... 2
  - 1 MBd Transistor Output Optocoupler .................................................. 2
  - 100 KBd Darlington Transistor Output Optocoupler ........................... 2
  - 20 MBd Digital Logic Gate Optocoupler ............................................. 3
  - 10 MBd Digital Logic Gate Optocoupler ............................................. 3
  - 8 MBd Digital Logic Gate Optocoupler ............................................... 4
  - 5 MBd Digital Logic Gate Optocoupler ............................................... 4
  - 1 MBd Digital Transistor Output Optocoupler ..................................... 5
  - 100 KBd Darlington Transistor Output Optocoupler ........................... 5
  - Integrated Gate Drive Optocoupler .................................................... 6
  - Miniature Analog Isolation Amplifiers ............................................. 6
  - Optocouplers with Integrated Functions .......................................... 7

**Hermetic and Hi-Rel Optocouplers** ..................................................... 9
  - For Military, Space, Life Critical and High Reliability Applications ...... 9
  - Screening per MIL-PRF-38534 ............................................................ 10
  - Quality Conformance Inspection ....................................................... 10

**Design Considerations** ........................................................................ 12
  - Insulation and Regulation of Optically Coupled Isolation Devices ..... 12
  - Common-Mode Transient Rejection .................................................. 17
  - LED Degradation Over Time ............................................................. 22
  - Guidelines for Printed Circuit Board Assembly and Layout .......... 22

**Digital Optoisolators: An Overview** .................................................... 26

**Digital Logic Interface/Level Shifting Applications** ................................. 28
  - TTL Interface with Series LED Drive ................................................ 28
  - Level Shifting/TTL Interface with Shunt LED Drive ......................... 29
  - Low Power 8 MBd CMOS Interface ............................................... 30
  - 25 MBd CMOS Interface ................................................................. 31
  - Low Power 100 kBd CMOS Interface ............................................. 32
  - Isolated 3 V Logic Interface/Battery Operated Applications .......... 33

**Data Communication Applications** ...................................................... 34
  - Isolated RS-232C/E Interface ......................................................... 35
  - Isolated 3.3 V RS-232 Interface ...................................................... 35
  - Isolated RS-485 Bus Interface ....................................................... 36
  - Isolated Device Net/CAN Communication Interface ...................... 37

Agilent Technologies offers a broad range of isolation products which provide performance features and benefits that are unmatched in the industry. Some of the leading product performance technologies that Agilent offers include:

- Dielectric Withstand Voltage Rating as high as 5000 Vac/1 min (per UL)
- First 3.3V optocoupler in the world
- Phototransistor optocouplers
- Worldwide Safety Approvals, including the highest Maximum Working Insulation Voltage ($V_{TORM}$) at 1000 V (per VDE)
- Common-Mode Transient Noise Immunity as high as 15 kV/µs (Minimum)
- A wide variety of surface mount and multi-channel packages, including the highest density optocouplers in the world.
- Lowest power dissipation optocouplers available, with input currents as low as 40 µA
- Highest speed optocouplers, with data rates as high as 25 MBd and propagation delays as low as 40 ns
- Wide operating temperature ranges for industrial and military environments
- A full line of hermetically-sealed optocouplers for high reliability applications. Available as commercial grade or Certified and Qualified to MIL-PRF-38534 Class H or K. DSCC Standard Microcircuit Drawings (SMDs) are available on all hermetic products.

Hermetic and Hi-Rel Optocouplers

For Military, Space, Life Critical and High Reliability Applications

Choose from Agilent Technologies’s broad line of high performance hermetic optocouplers to meet your military, space, life critical, and high reliability applications. There are four ceramic package styles to choose from: 8 and 16 pin Dual-In-line Packages, 20 terminal Leadless Ceramic Chip Carriers, and 16 pin Flat Pack packages. Available in most package styles are seven basic families of optocouplers: Analog Isolation Amplifier, Power Transistor Interface, High Speed Logic Gate Optocouplers, High Speed Transistor Optocouplers, High Gain Optocouplers, AC/DC to Logic Interface, and the Power MOSFET.

Agilent Technologies hermetic optocouplers are classified by the Department of Defense as hybrid microcircuits and are manufactured in Singapore on a MIL-PRF-38534 certified and qualified line. Agilent Technologies is listed as a qualified supplier for Classes H, E, and K product on the Qualified Manufacturers List, QML-38534. All product families are represented by commercial grade units and by high reliability tested units. To give maximum opportunity to utilize recognized DSCC parts, all 28 hermetic products are available on DSCC Standard Microcircuit Drawings (SMDs). Dual part marking of the Agilent part number and the DSCC Drawing is standard on all high reliability products. Each high reliability device is tested and guaranteed over the full military temperature range of -55°C to +125°C. Agilent offers a standard line of Class K devices to be procured that require no source control drawing to be generated. Note that while Agilent does not currently supply a certified Class K MOSFET or Analog Isolation Amplifier device, we can provide up-screening to most of the Class K requirements of MIL-PRF-38534.

Agilent Technologies is both DSCC certified and qualified to manufacture Class H (military approved) and Class K (space approved) hermetic optocouplers per the requirements of MIL-PRF-38534 Option 1 QCI (in-line inspection) or Option 2 (end-of-line inspection). All catalog Class H devices are processed per Option 1 QCI. Class K devices are processed per Option 2 QCI. Custom devices are available processed to either option.

### Quality Conformance Inspection

**Group A Testing**

Group A testing is satisfied per the in-line verification testing requirements of MIL-PRF-38534 for Class H devices.

Group A testing is performed per in-line sample testing requirements of MIL-PRF-38534 for Class K devices.

**Group B Testing**

Group B testing is satisfied by performing in-line inspection sample monitoring as required by MIL-PRF-38534 for Class H devices.

Group B testing per MIL-PRF-38534 is performed on each lot for Class K devices.

**Group C Testing**

Group C testing is performed only on the first inspection lot and as required to evaluate or qualify changes per the requirements of MIL-PRF-38534.

**Group D Testing**

Group D testing is not performed. Note that Group D requirements are satisfied by package evaluation at incoming inspection as allowed by MIL-PRF-38534.

Please be advised that Class H and class K devices have very similar Screening and Quality Conformance Inspection requirements as shown above. Class K devices, however, have substantially more stringent element evaluation and assembly criteria. The quality and reliability of a Class K device is achieved through the build process. Additional testing of a lesser grade product does not assure a comparative product.

### Hermetic Package Styles

- **Flat Pack**
- **Leadless Ceramic Chip Carrier**
- **8 Pin DIP**
- **16 Pin DIP**

**Options:**

- 100 Butt Cut Leads
- 200 Solder Dipped Leads
- 300 Gull Wing Lead Form (gold plated leads only)
Design Considerations

Insulation and Regulation of Optically Coupled Isolation Devices

The primary purpose of optocoupler devices is to provide both electrical insulation and signal isolation. The popularity of Agilent Technologies’ product offering can be accredited to cost-effective innovations in these areas. Yet there exists a surprising level of misunderstanding regarding these two terms from both vendor and user alike. The discrepancies that exist within the worldwide regulatory community add to the frustration level for many designers. This discussion attempts to help the designer capitalize on Agilent Technologies’ knowledge.

Insulation Defined

The electrical insulating capability of an optocoupler, sometimes referred to as withstand voltage, is determined by its ability to protect surrounding circuitry, as well as itself, against physical damage resulting from different voltage potentials. This potentially damaging phenomena can be system induced (e.g., motor rail voltage) or externally coupled (e.g., lightning pulse). The insulating material between input and output as well as the packaging technology are the primary determinants of withstand voltage capability. In contrast, signal isolation, although sharing some common causes, defines the ability of the optocoupler to prevent the distortion of data through the suppression and filtration of common-mode transients. A further discussion of signal isolation can be found in the section entitled “Common-Mode Transient Rejection.”

The effects of repeated long-term high-voltage stress between input and output of an optocoupler has continued to be an area of uncertainty. Much of the technical emphasis has been on the ability of optocouplers to withstand one-time short-term high-voltage transients (e.g., U.L. 1 minute dielectric voltage withstand rating). Agilent Technologies has conducted extensive operating life tests to determine the effects of continuous high-voltage stress, both transient as well as steady-state, on the degradation of insulating performance. On completion, the test data was analyzed to determine safe operating areas for steady-state input-output high-voltage stress. The boundary conditions, as shown in Figures 1, 2, 3, have been defined by Agilent as Endurance Voltage. The lower region refers to the safe operating area for the application of continuous steady-state ac and dc input-output voltage stress, or working voltage, and the middle region to transient voltage stress. Operation above these regions has shown to cause wear-out either in functionality or isolating capability and is not recommended. Endurance Voltage is based on the inherent properties of Agilent optocouplers that utilize unique packaging technologies and does not apply to products manufactured by other vendors. In addition, as these tests do not take into consideration particular equipment use conditions, Agilent recommends the designer consult the appropriate regulatory agency guidelines to determine applicable working voltage. For an in-depth discussion on Endurance Voltage, consult Agilent Application Note AN1074.

Regulatory Environment

Because electrical insulation is a function of safety, optocoupler performance, both at component and system levels, is often subject to regulatory requirements and approvals that vary according to country as well as industry. Most agencies are a mixture of governmental and private organizations with industry representation. Some common regulatory agencies are listed in Table 9.
INSULATION AND REGULATION

Category 1 Optocouplers

Category 2 Optocouplers:

Category 3 Optocouplers:

Figure 1. Recommended Safe Operating Area for Input-Output Voltage-Endurance Voltage for Category 1 Optocouplers.

Figure 3. Recommended Safe Operating Area for Input-Output Voltage-Endurance Voltage for Category 3 Optocouplers.

Figure 4. Optocoupler's Insulation Parameters.

WARNING: In all cases where regulatory compliance is required, working voltage as defined by the regulatory agency cannot be exceeded.
Currently, little conformity exists between the various agencies regarding mechanical configurations and electrical test requirements. Within the European Union, however, standardization of equipment as well as component level specifications is in progress. In the interim, testing and approval according to equipment type and environmental factors must be obtained according to the control documents of each country. The International Electrotechnical Commission (IEC), with worldwide representation, provides a forum for generating technical standards. The European Committee for Electrotechnical Standardization (CENELEC), has European Commission authority to adopt IEC standards as European Norms (EN), with the force of law.

**Common Terms**

**External Clearance**
The shortest distance through air, between conductive input and output leads, measured in mm. Refer to Figure 4.

**Comparative Tracking Index (CTI)**
Outer molding material characterization in the presence of aqueous contaminants. The higher the CTI value, the more resistant the material is to electrical arc tracking. CTI is often used with creepage by safety agencies to determine working voltage.

**External Creepage**
The shortest distance along the outside surface, between input and output leads, measured in mm. Refer to Figure 4.

**Dielectric Insulation Voltage Withstand Rating**
The ability to withstand without breakdown a 60 second application of a defined dielectric insulation voltage between input and output leads.

**Distance Through Insulation**
Distance between the photomitter and photodetector inside optocoupler cavity (also called internal clearance). Refer to Figure 4.

**Installation Class**
I  Equipment in closed systems (e.g., telecom) protected against over-voltage with devices such as diverters, filters, capacitors, etc.
II  Energy consuming equipment (e.g., appliances) supplied through a fixed installation.
III  Primarily equipment in fixed installations (e.g., fixed industrial equipment).
IV  Primary supply level for industrial factories.

**Insulation**
Operational - required for correct equipment operation but not as a protection against electric shock.
Basic - protects against electric shock.
Supplementary - independently applied to basic insulation to protect against shock in the event of its failure.
Double - composed of both basic and supplementary.
Reinforced - A single insulation system composed of several layers (e.g., single and supplementary).

**Internal Clearance**
See Distance Through Insulation.

# INSULATION AND REGULATION

**Internal Creepage**
The shortest border distance between two separate insulating materials measured between emitter and detector.

**Material Group** (see Comparative Tracking Index)
- I  $600 < CTI$
- II  $400 < CTI < 600$
- IIIa  $175 < CTI < 400$
- IIIb  $100 < CTI < 175$

**Partial Discharge**
Electric discharge that partially bridges the insulation between two electrodes. Agilent supports partial discharge measurements per VDE0884, a technique developed to evaluate the integrity of insulating materials. VDE's philosophy is that partial discharge testing offers advantages over Dielectric Withstand Voltage testing, which might adversely affect the insulating material, and over through insulation distance requirements which not only increase manufacturing costs but also do not necessarily result in acceptable insulating capability.

**Pollution Degree**
1. Nonconductive pollution only.
2. Only occasional, temporary conductivity due to condensation.
3. Frequent conductive pollution due to condensation.
4. Persistent conductive pollution due to dust, rain or snow.

**Rated Mains Voltage**
Primary power voltage declared by manufacturer. Used to categorize optocoupler maximum allowable working voltage.
Common-Mode Transient Rejection

Circuit designers often encounter the adverse effects of common-mode noise in a design. Once a common-mode problem is identified, there are several ways that it can be resolved. However, common-mode interference manifests itself in many ways; therefore, it may be hard to determine whether it is the cause of a circuit’s misbehavior. If a system is connected and running but only produces erroneous data, common-mode noise may be the reason. This section describes sources of common-mode problems, presents possible solutions, and highlights the technology that Agilent Technologies’ Components Group uses to produce opto-isolators with superior Common-Mode Performance.

Common-mode rejection (CMR) is a measure of the ability of a device to tolerate common-mode noise. Agilent specifies common-mode rejection as **common-mode transient rejection** (CMTR). CMTR describes the maximum tolerable rate-of-rise (or fall) of a common-mode voltage (given in volts per microsecond). The specification for CMTR also includes the amplitude of the common-mode voltage ($V_{CM}$) that can be tolerated. Common-mode interference that exceeds the maximum specification might result in abnormal voltage transitions or excessive noise on the output signal. (CMTR is slightly different than common-mode rejection ratio CMRR, often used for analog devices and commonly specified in dB as the ratio of the differential-mode gain to the common-mode gain.)

Agilent optocouplers rely on two key technical strengths to achieve high CMTR. The first is use of a proprietary, low-cost Faraday shield which decouples the optocoupler input side from the output side. The second method is by unique package design which minimizes input-to-output capacitance. The importance of these two strengths is explained as follows.

Figure 5 illustrates a Common-mode transient pulse ($V_{CM}$).

Figure 6a and 6b show interference circuit models for two types of possible common-mode failure mechanisms for a single-transistor optocoupler. The dashed lines are shown to indicate external components added to the optocoupler. $V_{CM}$ represents a voltage spike across the optocoupler isolation path between the output-side ground ($V_{G2}$) and input-side ground ($V_{G1}$). $V_{DM}$ represents a signal voltage applied across the input side.

**Figure 5.** Illustration of $V_{CM}$ Common-Mode Pulse.

**Figure 6a.** Interference Circuit Model.
COMMON-MODE TRANSIENT REJECTION

Referring to Figure 6a the parasitic distributed capacitance $C_{IS}$, which might tend to couple transient current into the transistor base node (for example when the transistor is in the “off” state) terminates on an internal Faraday shield. Therefore the transient current, $I_{CM}$, gets diverted to output ground ($V_{O2}$). Referring to Figure 6b, the parasitic distributed capacitances, $C_{IA}$ and $C_{IC}$ are shown across the LED anode-to-ground ($V_{G2}$) and LED cathode-to-ground ($V_{G2}$) respectively. Because the LED anode is at a relatively higher impedance than the cathode (i.e., $R_{LED}$ to ground) current at this point will tend to be modulated slightly during CM transients. For instance, if the LED is on, then during a positive transient (i.e., $dV_{CM}/dt > 0$) current will be diverted away from the LED. For fast enough transients, this may turn the LED off. (If $R_{LED}$ is connected to the LED cathode side then $C_{IC}$ provides a parasitic path to divert current towards or away from the LED.) This type of failure is avoided by ensuring that $C_{IA}$ and $C_{IC}$ are small.

Figure 7 shows the possible effect on the output voltage level of an optocoupler due to a common-mode pulse. The output is shown (successively) in the high and low states. (This might be observed if $R_{LED}$ were connected as in Figures 6a, 6b.)

**Figure 6b. Interference Circuit Model.**

**Figure 7. Common Mode Interference Effect.**
As long as the amplitude $V_{CM}$ and value of $dV_{CM}/dt$ are less than the ratings for the optocoupler being used, $V_{OH}$ will remain above 2 V (maximum TTL $V_{IH}$) and $V_{OL}$ will remain below 0.8 V (minimum TTL $V_{IL}$). Note that the slight perturbations in output voltage occur sometime after the input pulse which causes them, due to the non-zero response time of the output transistor to the “perturbation signal.”

Common-mode signals can originate from several different sources. A full bridge power inverter, shown in Figure 8, is a good example of an application that can exhibit large amounts of common-mode noise. Full-bridge inverters are commonly found in motor-speed control and switching power supply applications. The power inverter is generally used to produce an ac output from a dc input. In a full-bridge inverter application like that shown in Figure 8, the source of one set of transistors (A1, B1) is attached to the drain of a second set of transistors (A2, B2). When transistor set A turns on, set B turns off. Current flows from the positive supply, through transistor A1, through the load, and through transistor A2. When set B turns on, set A turns off, and the polarity of the current through the inductive load is reversed.

How does this operation create a common-mode problem? The input of each gate drive circuitry is referenced to the ground of the digital control circuitry; the output common, on the other hand, is floating and referenced to the source of its associated power transistor. The floating commons of the upper gate drive circuits rapidly switch between the positive and negative power supplies. This rapid switching creates a large voltage swing across the input to output of the gate drive circuitry. As an example, a half-bridge circuit that switches between +250 V and -250 V in 100 ns creates a common-mode transient signal of 5000 V/µs with an amplitude of 500 V (see Figure 9). The device that carries the control information to each MOSFET must be able to withstand this level of common-mode interference. Although this example may seem extreme, it is a fact that engineers continue to use faster-switching transistors to increase motor efficiency. Power MOSFETs, for example, are commonly used in power inverter applications because they are capable of high frequency, high power switching. The fast switching speeds of the transistors, however, can generate common-mode signals with very high rates of change ($dV_{CM}/dt$).

The common-mode signal rate of rise can also be affected by the reverse recovery characteristics of diodes D1 and D2 in the power
common-mode transient rejection

The voltage and current waveforms shown in Figure 10 illustrate what happens when Q1 turns back on. As Q1 starts to turn on, the current through D2 begins to decrease. The current through D2 continues to decrease and actually goes negative for a short time due to the storage of minority carrier charge in its junction. It is when this charge has been depleted that D2 begins to turn off and V_CM begins to increase. If D2 turns off very quickly, V_CM can also rise very quickly, generating a large common-mode transient signal.

For the particular case of driving the gate of an IGBT or power MOSFET in a power inverter, the HCPL-3120 IGBT/MOSFET gate drive optical isolator is an effective solution for common-mode problems, providing protection against common-mode transients with slew rates as fast as 15 kV/µs at V_CM as high as 1500 V.

High electrical noise levels can also contribute to common-mode problems. A significant amount of electrical noise is found in industrial environments as a result of the starting and operating of electric motors. When a large motor first turns on, it normally requires a large in-rush current to reach operating speed. This large current spike can generate a significant amount of electrical noise in its own and nearby systems. Even the electric motors in a typical household environment vary in size from fractional to low integral horsepower units and are often noisy ac-operated or brushed dc-motors. Other sources of electrical noise include microwave ovens, welding equipment, and automobile ignitions.

Common-mode noise can enter a system through conductive, inductive, or capacitive coupling.

An example of a “conducted”
Noise voltage is the difference in ground potential that may exist between two connected systems in a plant. The two systems may experience a small voltage difference between their ground references. This voltage difference might cause a ground-loop current to flow. If the impedance of the path through which the ground-loop current flows is large enough, a significant amount of interference will result. Capacitive or inductive coupling may occur when signal wires run close to ac power cables. Electromagnetically induced interference (EMI) can also be coupled from adjacent signal lines or nearby equipment, especially in factory environments. Other sources of common-mode noise that can be coupled into a system include lightning strikes and electrostatic discharge (ESD).

Optical isolation is a useful technique for reducing common-mode interference. Optocouplers, like transformers and capacitively-coupled devices, provide isolation between the input and output of a system. Transformers, by virtue of their high primary-to-secondary capacitance, tend to have lower CMTR capability. Capacitively-coupled devices tend to have poor CMTR capability (since in these devices fast, transient common-mode pulses pass across the coupling capacitor and are not filtered out.) Optocouplers, having low input-to-output capacitance, typically provide better common-mode rejection than transformers or capacitively-coupled devices. The CMR specification of an optocoupler ranges up to $V_{CM} = 1500$ V amplitude and up to 15,000 V/µs rate of change of $V_{CM}$ for high-CMR products.

Another advantage of optocouplers lies in the area of EMI generation and susceptibility. Transformers typically radiate electromagnetic interference (EMI) and are susceptible to magnetic fields. Capacitively-coupled devices generate ground-loop current, thus generating EMI. Optocouplers use light for data transmission; additionally, they effectively eliminate ground-loop current. Therefore, they do not radiate nor are they affected by stray magnetic fields. This ability is well-recognized in the European Community where systems designers need to achieve system-level standards (now adopted as EN50081/EN50082 which set limits on the amount of acceptable EMI a system radiates or to which it is immune.)

A technique which may be used to further enhance CMTR is an “LED split-resistor” technique as shown in Figure 11; (note that the $V_{DSW}$ which would appear between the top and bottom $R_{LED}$ has not been shown in this “ac equivalent circuit”). By using two LED-resistors (instead of one) the current change at the anode of the LED is nearly canceled by the current change at the cathode, thus tending to keep the LED current constant. This makes the optical isolator more immune to CM transients where $C_{LA}$ and $C_{LC}$ limit CMTR.
LED DEGRADATION

LED Degradation over Time

One concern for optocoupler lifetime is that LED light-output (LOP) decreases over time. Generally, light-output degradation gets worse with increasing operating temperature and operating LED current. A worst-case scenario is that over time, as the LED becomes dimmer, the LOP will fall below the minimum value needed for a part to switch properly. Agilent Technologies, an industry leader in LED technology, tests LOP degradation under accelerated conditions in order to provide designers with information on the expected operating lifetime of optocouplers. Optocouplers which have an input driver IC are designed such that the driver IC sets the proper input IF, guardbanding for expected LED LOP degradation over the life of the optocoupler. (Examples are the HCPL-3700, HCPL-7101, and HCPL-7840.) On the other hand, optocouplers requiring an input current-setting resistor (i.e., without an input driver IC) require that the circuit designer guardband the minimum recommended operating IF by an amount sufficient to account for expected LOP degradation.

Agilent has undertaken testing of LED degradation for periods of continuous operation up to at least 10,000 hours for various LEDs used in Agilent optocouplers. Figures 12a and 12b show the normalized light output over a 10,000 hour period for Gallium Arsenide Phosphide (GaAsP) and Aluminum Gallium Arsenide (AlGaAs) LEDs respectively.

Figure 13 shows LOP as a function of IF for a GaAsP LED under operating conditions of IF = 20 mA at an ambient temperature of T_a = 125°C. Curves are shown for t = 0 hours and t = 10,000 hours of continuous operation.

Optocouplers which use the GaAsP and AlGaAs LEDs are listed in Figures 12a and 12b. Figure 14 illustrates how, based on knowledge of initial and post-stress LOP vs. IF, (for a GaAsP LED) a minimum guardbanded IF can be determined to provide for LOP degradation over the life of the LED. For this case, the minimum recommended IF at t = 0 hours (IF(min)) of 5 mA is guardbanded for 10,000 hours of operation to a value of 6.1 mA.

Note that in Figure 14 if the LOP vs. IF curves were linear over the range between IF(min) and IGB(min) (minimum IF guardbanded for t = 10,000 hours) then the amount of guardbanding (percent change) would be equal to the amount of LOP degradation (percent change). Since in our case the curve is “concave up” the amount of guardbanding is slightly less than the percent change in LOP between t = 0 and t = 10,000 hours. Figure 15 (which is a plot of the slope of the (t = 0) curve in Figure 14), shows that the slope is increasing up to about IF = 20 mA, at which point it...
LED DEGRADATION

flattens out and begins decreasing.

By empirically modeling the typical GaAsP LOP vs. $I_F$ curve and applying knowledge of worst-case (-3 $\sigma$) degradation over time, guardbanded $I_{GB(min)}$ for a typical LED can be reduced to the following equation:

$$I_{GB(min)} = \frac{I_{F(min)}}{\delta} \approx I_{F(min)} \times 1.214$$

where,

$I_{F(min)}$ = minimum recommended $I_F$ at $t = 0$ hours.

$I_{GB(min)}$ = minimum guardbanded $I_F$ after $t = 10$ khours.

$a = 1.3$ (empirical curve - fit)

$\delta =$ Post-stress LOP Factor

($\approx 0.784$ for 10 khours, $T_A = 125^\circ$C, $I_F = 20$ mA)

This equation applies well when $I_F$ is approximately constant.

Example: To calculate the appropriate $I_{GB(min)}$ for an HCPL-3120 note that $I_{F(min)} = 7$ mA. Applying the above relationship for 10 khour guardbanding,

$I_{GB(min)} = 8.50$ mA.

![Figure 12a. Normalized LED Light Output (LOP) vs. Time for GaAsP LED (Stress $I_F = 20$ mA, $T_A = 125^\circ$C).](image1)

![Figure 12b. Normalized LED Light Output (LOP) vs. Time for AlGaAs LED (Stress $I_F = 25$ mA, $T_A = 125^\circ$C).](image2)

![Figure 13. Typical GaAsP LED Light-Output (LOP) vs. $I_F$ After 0 khours and 10 khours of Continuous Operation at $125^\circ$C, $I_F = 20$ mA.](image3)
Factors which will increase expected LED guardbanded-operation times are:

1. **Operation at lower $I_F$:** $I_F$ decreases less with reduced operating $I_F$. Therefore, operation at $I_{GB} < I_F < 20$ mA will result in guardbanded operating lifetimes longer than 10 khours. This is due to the fact that lower operating $I_F$ reduces junction temperature ($T_J$) which subsequently reduces the amount of degradation over time. Generally, the lower the operating $I_F$, the lower the percent degradation will be as a function of time.

2. **Operation at Duty Factor (DF) less than 100%** will increase guardbanded operating lifetimes. For any particular duty factor, the new guardbanded lifetime becomes:

$$\frac{\text{lifetime}_{\text{continuous}}}{DF(\%)} \times 100$$

3. **Operation at ambient temperature $T_A < 125^\circ C$** will also decrease the amount of LOP degradation (again, due to decreased $T_J$) increasing operation lifetime.

Agilent also has LED degradation data available for other LED types. AlGaAs LEDs tend to be more linear than GaAsP LEDs and display less degradation over time than GaAsP. Therefore the calculations used here can be applied with confidence to optocouplers using AlGaAs LEDs. For further specific questions, please contact your local Agilent Technologies’ sales representative.
LED DEGRADATION

Guidelines for Printed Circuit Board Assembly and Layout

Agilent optocouplers are suitable for automatic printed circuit board (PCB) assembly operations including surface mount assembly. The following guidelines are recommended for proper operation and long term reliability of Agilent optocouplers.

Solder Reflow Process: Only one soldering operation is recommended within the thermal profile shown in Figure 16. With infrared lamp heating, use precautions to avoid localized temperature rise in the resin. Also, the resin should not be immersed in the solder. To prevent chloride corrosion of the lead frame, halide fluxes should not be used.

Wave Soldering: The maximum solder temperature allowed is 260°C for 10 seconds, with the solder 1.6 mm below the seating plane.

Solvent Cleaning: The solvent temperature and immersion time should not exceed 45°C and three minutes respectively. For ultrasonic cleaning, environmentally safe solvents such as ethyl and methyl alcohol are recommended.

ESD Precautions: Standard electrostatic discharge precautions should be taken in handling and assembly of the optocouplers to prevent damage or degradation of the device.

Printed Circuit Board Layout: An optocoupler performs reliably only in a correctly designed circuit. In most digital optocouplers the amplifier at the output is required to operate with the very low photocurrent from the photodetector. Consequently these amplifiers can be sensitive to electrical disturbances. It is therefore necessary to have proper shielding and bypassing of the VCC and Ground traces. Bypassing closely to each of the optocouplers VCC-to-Ground pins with low-inductance ceramic capacitor is recommended as shown in Figure 17.

Figure 17 shows an optional PCB layout for a high speed digital optocoupler for improving electrical noise immunity. The optional VCC and Ground traces between the pin rows of the optocoupler help shield the output circuitry from electrical disturbances on the input pins, thus improving common-mode rejection.
Digital Optoisolators: An Overview

Introduction
Agilent Technologies offers a wide array of Optoisolators for noise rejection, ground loop current elimination, and high voltage isolation for digital data transmission and communication applications. The product offering includes low speed (100 kbit/s to 1 M bit/s) split Darlington or single transistor type optoisolators to high speed 25 M bit/s cascaded amplifier stage optoisolators with Schottky transistor or CMOS output stage.

Description
Figure 1 shows a Photodiode/Transistor Optoisolator where a PIN photodiode detector is coupled to a single transistor amplifier output stage (e.g. HCPL-4504). Compared to a typical phototransistor optoisolator, a PIN photodetector diode reduces the base-collector “Miller” capacitance and allows operability at a much higher speed.

Figure 2 shows a Split Darlington Output Stage, where an emitter-follower stage is added between a PIN photodiode and the output amplifier. This allows the optoisolator to be driven at a much lower input drive current, as low as 40 mA for the HCPL-4701/HCPL-4731 family or 0.5 mA for the 6N139 family. This allows much higher current transfer ratio (CTR) or current gain at the output, and TTL/CMOS gates can be easily driven.
Figure 3 shows a photodiode cascaded amplifier, coupled to a Schottky transistor, open collector output stage. In order for an open collector output stage to function, a pull-up resistor is required at the output of the Optoisolator.

Figure 4 shows a photodiode and cascaded amplifier, coupled to a totem pole output stage. This type of output stage eliminates the necessity of using a pull-up resistor at the output. The outputs can sink or source current allowing higher output power drive capability.

Figure 5 shows a push-pull CMOS output stage. These types of optoisolators are designed to achieve highest speed performance (up to 25 M bit/s for HCPL-7721/7720). The amplifier stage presents very low input impedance to the photodiode, and does not become saturated, while allowing the signal to be amplified several folds through the amplifier stages, allowing operation at relatively low LED drive currents (2 to 5 mA).

*PIN 3 IS THE ANODE OF THE INTERNAL LED AND MUST BE LEFT UNCONNECTED FOR GUARANTEED DATA SHEET PERFORMANCE. C1, C2 = 0.01 TO 0.1 µF
Digital Logic Interface/Level Shifting Applications

TTL Interface with Series LED Drive

Description
The circuit shown is an interface between two TTL gates using an active output (totem pole) optocoupler, the HCPL-2201. A series switching circuit drives the optocoupler LED. The designer chooses $R_{IN}$ to agree with the equation shown in the schematic. The active output of the HCPL-2201 can be directly connected to a TTL gate, and no pull-up resistor is required. The HCPL-2201 can sink enough current to handle up to 16 LSTTL or 4 TTL loads.

Performance of Circuit
- Maximum optocoupler propagation delay: 300 ns (refer to alternative Agilent parts for lower propagation delay times)
- Typical signaling rate: dc to 5 MBd (refer to alternative Agilent parts for higher speeds)
- Typical optocoupler LED drive current: 2 mA

Benefits
- No pull-up resistor required on the optocoupler output interface
- Low power dissipation on the optocoupler input circuit
- Up to 20 V supply voltage for the HCPL-2201

Alternative Agilent Parts
1) HCPL-07XX, HCPL-2730/1, HCPL-4701, 6N138/9, CNW138/9 Low Input Current Optocouplers
2) HCPL-0201/11 Small-Outline Logic-Gate Optocoupler
3) HCPL-52XX Hermetically Sealed Logic-Gate Optocoupler
4) CNN2201/11 Widebody Logic-Gate Optocoupler
5) HCPL-2230/1 Dual-Channel Logic-Gate Optocoupler
6) HCPL-05XX, HCPL-2530/1, HCPL-135/6, 6N135/6 High Speed Optocouplers
7) HCPL-250L/260L/270L, HCPL-050L/060L/070L 3.3 V Optocouplers
**Description**

The above circuit shows how a 0 to 5 V logic signal can be level shifted to a -15 to 0 V signal. The circuit can safely be used for level shifting up to ±800 V. The circuit uses an open collector output logic gate, the 74LS405, to drive the LED of the HCPL-4502/3 optocoupler. The HCPL-4502/3 also has an open-collector output. The designer chooses $R_{IN}$ to agree with the equation shown in the schematic. This equation sets the value of the optocoupler LED forward current. The output of the HCPL-4502/3 requires a pull-up resistor, $R_L$. The current-transfer ratio (CTR) of the optocoupler determines the maximum amount of current the optocoupler output can sink while maintaining the output voltage (between pins 5 and 6) of 0.5 V or less.

**Performance of Circuit**

- Maximum optocoupler propagation delay: 2 µs (refer to alternative Agilent parts for lower propagation delays)
- Typical signaling rate: dc to 1 MBd (refer to alternative Agilent parts for higher speeds)
- Typical optocoupler LED drive current: 10 to 16 mA
- Maximum output supply voltage (pins 8-5): 30 V
- Minimum CMR: 15 kV/µs slew rate, 1500 V peak

**Benefits**

- Reduces transient immunity problems
- Convenient way of replacing pulse transformer for high-voltage level shifting

**Alternative Agilent Parts**

1) HCPL-07XX, HCPL-2730/1, HCPL-4701, 6N138/9, HCNW138/9 Low Input Current Optocouplers
2) HCPL-55XX Hermetically Sealed High Speed Optocoupler
3) HCPL-0710 SO-8 High Speed CMOS Optocoupler
4) HCPL-250L/260L/270L, HCPL-050L/060L/070L 3.3 V Optocouplers
DIGITAL INTERFACE
Low Power 8 MBd CMOS Interface

Description
A CMOS-to-CMOS interface is possible with Agilent optocouplers. The above circuit shows an interface circuit for 8 MBd applications. Over the temperature range a CMOS CD4050 Hex Buffer can source about 0.7 mA (minimum), which is sufficient to drive the HCPL-2300/HCPL-0300 optocoupler. The 20 pF capacitor allows peaking currents to assist the LED turn on and off quickly.

Performance of Circuit
• Optocoupler LED current: 0.5 mA minimum
• Typical signaling rate: dc to 8 MBd

Benefits
• Low power consumption
• Simple interface

Alternative Agilent Parts
1) HCPL-7721/7720/7710 High Speed CMOS Optocoupler
2) HCPL-0721/0720/0710 Small Outline High Speed CMOS Optocoupler
DIGITAL INTERFACE
25 MBd CMOS Interface

Description
Up to 25 MBd CMOS-to-CMOS interface is possible with the HCPL-7721 optocouplers. The above circuit requires only a bypass capacitor on each of the HCPL-7721 input-side and output-side power supply pins.

Performance of Circuit
- Typical logic low input power supply current for HCPL-7721: 1.5 mA
- Typical logic low input power supply current for HCPL-7721: 7 mA
- Typical HCPL-7721 signalling rate: dc to 25 MBd
- Typical HCPL-7721 pulse-width distortion: 3 ns
- Typical HCPL-7721 propagation delay: 20 ns

Benefits
- Lower power consumption
- Very simple interface

Alternative Agilent Parts
1) HCPL-0721: SO8 package
2) HCPL-7720/0720: 25 MBd, 8 ns PWD CMOS interface optocoupler
3) HCPL-7710/0710: 25 MBd, 8 ns PWD CMOS interface optocoupler
DIGITAL INTERFACE
Low Power 100 kBd CMOS Interface

Description
A CMOS-to-CMOS interface is possible with Agilent optocouplers. The above circuit shows a cost-effective interface for 100 kBd applications. The 74HCT04 CMOS Hex Inverter that drives the optocoupler LED can source and sink up to 4 mA current. The 6N139 optocoupler requires only 0.5 mA LED current for operation. The signal diode across resistor R₁ protects against common-mode transient voltages and is optional. The output circuit uses a 74HCT08 so that the signal from \( V_{IN} \) to \( V_{OUT} \) is not inverted.

Performance of Circuit
- Minimum optocoupler LED turn-on current: 0.5 mA (The HCPL-4701 optocoupler requires only 40 µA)
- Typical signaling rate: dc to 100 kBd
- Minimum optocoupler current transfer ratio: 400%

Benefits
- Low power consumption
- Simple interface

Alternative Agilent Parts
1) HCPL-4701 Very Low Power High Gain Optocoupler
2) HCPL-2730/1 Dual Channel High Gain Optocoupler
3) HCPL-0731 Small Outline High Gain Optocoupler
4) HCPL-57XX, HCPL-67XX, 6N140 Hermetically Sealed High Gain Optocoupler
5) HCPL-270L 3.3V Optocoupler
**DIGITAL INTERFACE**

Isolated 3 V Logic Interface/Battery Operated Applications

---

**Description**

The HCPL-4701 low-power optocoupler is used for 3 V-to-3 V Logic interface across an isolation barrier. Only 40 µA of LED current (I_{LED}) is required to turn-on the optocoupler. Typical power for dissipation for just the optocoupler is 135 µW at I_{LED} = 40 µA, and 965 µA at I_{LED} = 500 µA.

**Performance of Optocoupler**

- Typical optocoupler current transfer ratio: 3500% at I_{LED} = 40 µA
- Input current for optocoupler turn-on: 40 µA

**Benefits**

- Low power dissipation

**Alternative Agilent Parts**

1) HCPL-4731 Dual Low Power Optocoupler
2) HCPL-070A SO-8 Low Power Optocoupler
3) HCPL-073A SO-8 Dual Channel Low Power Optocoupler
4) HCPL-050L/060L/070L, HCPL-250L/260L/270L 3.3 V Optocouplers
Description
The above schematic shows a very simple RS-232C data communication isolation interface using a 6N139 optocoupler. This circuit operates with an LED forward current of 0.5 mA when the input is at 3 V. The 1N4150 diode protects the LED during negative signal voltages. Since a low diode current is used to operate the 6N139, the twisted pair line can be up to 120 m. However, the data rate may have to be lowered to account for slower charging and discharging of the total line capacitance.

Performance of Circuit
• RS-232C link twisted pair cable length: up to 120 m for low data rates
• Typical optocoupler propagation delay: 20 µs

Benefits
• Simple, low cost isolated interface
• Meets worldwide regulatory standards for isolation

Alternative Agilent Parts
1) HCPL4701, 6N138/9, 4N45/6, HCPL-2730/1 High-Gain, Low Input Current Optocoupler
2) HCPL-0700/1, HCPL-0730/1, HCPL-M700/1 Small Outline High-Gain, Low Input Current Optocoupler
3) HCPL-270L/HCPL-070L 3.3V, 100 kBd Optocoupler
**Description**
The above isolated RS-232 circuit uses two high-speed 3.3 V optocouplers that can switch up to 15 MBd signals. An isolated power supply is required to power the DS14C335 driver/receiver integrated circuit.

**Performance of Circuit**
- Typical signaling rate: up to 15 MBd
- Optocoupler LED drive current: 5 mA
- Typical Optocoupler Transient Rejection: 10,000 V/µs slew rate, 50 V peak

**Benefits**
- Compact design with small outline optocouplers
- Prevents common-mode transients from interfering with the signal
- Low power dissipation

**Alternative Agilent Parts**
1) HCPL-263L/HCPL-063L Dual Low Power Optocoupler
2) HCPL-250L or HCPL-270L for low data rate applications
**Description**

The above isolated RS-485 interface circuit uses the HCPL-26XX High Speed CMOS optocoupler, which can transmit digital signals faster than 10 MBd. An isolated 5 V power supply is required to power the RS-485 bus side of the circuit.

**Performance of Circuit**

- Typical optocoupler signaling rate: greater than 10 MBd
- Typical optocoupler propagation delay: 28 ns
- Typical optocoupler pulse-width distortion: 2 ns

**Benefits**

- Low signal distortion
- Good transient immunity

**Alternative Agilent Parts**

1) HCPL-2400/30 High Speed Optocoupler
2) HCPL-7721/7720/7710 High Speed CMOS Optocoupler
3) HCPL-54XX Hermetically Sealed High Speed Optocoupler
4) HCPL-0721/0720/0710 SO-8 High Speed CMOS Optocoupler
5) HCPL-260L/263L 3.3V Optocouplers
DATA COMMUNICATIONS
Isolated Device Net/CAN Communication Interface

Description
DeviceNet, a factory floor communication network standard, sometimes may require connecting devices to be electrically isolated. The HCPL-0720 high speed CMOS optocoupler with a 40 ns maximum propagation delay time meets the DeviceNet physical layer specification.

Performance of Circuit
- Typical data rate (NRZ): Up to 12 Mbit/s
- Compatible with 5 V CMOS and TTL logic gates
- Minimum common mode transient immunity: 10 kV/µsec at VCM = 1000 V

Benefits
- Direct interface to the optoisolator input and output (No external resistors necessary)
- Speed optimized for Profibus, RS-485, DeviceNet/CAN
- Small outline surface mount package offers space/footprint saving
- Performance guaranteed over industrial temperature range (0 to 85°C)

Alternative Agilent Parts:
1) HCPL-7721/7720/7710 High Speed CMOS Optocoupler
2) HCPL-0721/0720/0710 SO-8 High Speed CMOS Optocoupler
ANALOG APPLICATIONS
Isolated 4-20 mA Analog Current Loop Transmitter/Receiver

Description
The HCNR200/1 Analog Optocoupler isolates both the transmitter and receiver circuit from the 4 - 20 mA Analog Current Loop. One important feature of this circuit is that the loop side of the circuit is powered by the loop current. No isolated power supply is required.

Performance of Circuit
- Converts an analog voltage input to an analog current and vice versa
- HCNR200/1 nonlinearity: 0.1%
- HCNR201 gain tolerance: ±5%

Benefits
- Low-cost simple circuit
- No isolated power supply needed on the 4 - 20 mA side of the circuit

Alternative Agilent Parts
1) HCPL-4100 20 mA Current Loop Transmitter
2) HCPL-4200 20 mA Current Loop Receiver

NOTE: The two OP-AMPS shown are two separate LM158, and NOT two channels in a single DUAL package; otherwise, the LOOP side and input side will not be properly isolated.
DATA COMMUNICATIONS
Isolated 20 mA Current Loop Interface

**Description**
The above half-duplex, point-to-point, multi-drop, 20 mA current loop configuration can alternately transmit bi-directional data over two wires. Only one current source is required. Each isolated station with an HCPL-4100 transmitter and HCPL-4200 receiver optocouplers provides excellent common-mode rejection.

**Performance of Circuit**
- 1 mA noise margin in the "space" state
- 8 mA noise margin in the "mark" state
- Typical signal rate and distance: 40 m at 100 kBd; over 200 m at 10 kBd

**Benefits**
- Maintains data integrity
- Simple data transmission system for industrial applications
Description
The above differentially driven circuit can use up to eight 6N138 optocouplers at various receivers along the 90 m line. All stations are isolated. The first station would draw approximately 2.7 mA current, and the last station 1.8 mA of LED drive current. The output grounds of the optocoupler may be electrically separate.

Performance of Circuit
- Typical signaling rate: 18 kBd (faster signaling rates can be obtained with HCNW139 and 6N139)
- Typical optocoupler propagation delay time: \( t_{PHL} = 2 \mu s \); \( t_{PLH} = 20 \mu s \)
- Up to 90 m distance

Benefits
- Simple, low-cost, multidrop circuit for low signaling rates

Alternative Agilent Parts
1) HCPL-0700/01/30/31, HCPL-M700/1, HCNW138/9, and HCPL-2730/31 Low-Input Current Optocouplers
2) HCPL-57XX, HCPL-67XX, and 6N140 Hermetically Sealed Low-Input Current Optocouplers
3) HCPL-2300 High Speed, Low Input Current Optocoupler
Description
A balanced RS-422 line driver differentially drives a twisted pair line. Two HCPL-2300s provide balanced signal direction for this line. The thresholds of the HCPL-2300 will be nearly equal, providing symmetrical signal detection level. Since the propagation delays of the two optocouplers are similar, the pulse-width distortion for this scheme will be quite low for considerable line lengths. The Exclusive-Or flip-flop circuit at the optocoupler output increases CMR protection to an extremely high level and balances the propagation delays. For less demanding noise environments, only one HCPL-2300 with no EX-OR flip-flop may be used. The maximum data rate, however, will be somewhat lower.

Performance of Circuit
- Signaling rate: > 10 MBd at 100 m line length
- Common mode rejection: > 15,000 V/µs

Benefits
- Very high common-mode transient rejection
- Data transmission for up to 1 km distance

Alternative Agilent Parts
HCPL-2602/12 High CMR Line Receiver
Description
This is a differential receiver using a dual-channel HCPL-2630 Optocoupler. The receiver circuit can handle data up to 10 Mbd for short line lengths. The capacitance of the twisted-pair wire introduces a propagation delay and, as a result, the data rate decreases with increasing line length. At the optocoupler output, an optional Exclusive-Or circuit can be used to increase CMR and to balance the propagation delays.

Benefits
• Dual channel optocoupler reduces boardspace
• Balanced circuit increases CMR performance thereby eliminating or reducing transient interference

Performance of Circuit
• Signaling rate: up to 10 MBd
• Optocoupler common mode rejection: 10,000 V/µs

Alternative Agilent Parts
1) HCPL-0631 Small Outline, Dual-Channel, High Speed Optocoupler
2) HCPL-4661 High-CMR, Dual-Channel Optocoupler
3) HCPL-56XX Hermetically Sealed High Speed Optocouplers
Description
The above circuit converts a single-ended signal to a split-phase signal with a 75159 Tri-State Line Driver and dual-channel HCPL-4661 High CMR Optocoupler. When Input Enable goes low, the lower channel of the optocoupler operates the "strobe" input of the 75159 to make both outputs open.

Performance of Circuit
- Optocoupler signaling rate: up to 10 MBd
- Optocoupler CMR: 15,000 V/µs at 1000 V peak (typical)

Benefits
- Higher data rate than a current source pull-up
- High CMR performance reduces or eliminates transient noise

Alternative Agilent Parts
1) HCPL-063N SO-8 High CMR Dual Channel Optocoupler
2) HCPL-2631 Dual Channel High Speed Optocoupler
3) HCPL-0631 Small Outline, Dual Channel Optocoupler
4) HCPL-56XX Hermetically Sealed High Speed Optocouplers
5) HCPL-053L/063L/073L, HCPL-253L/263L/273L 3.3V Optocouplers
**Description**

The above illustration is an unbalanced line receiver using the integrated voltage-clamp input optocoupler, HCPL-2602. The circuit is unbalanced because the termination impedance is different for both “ends” of the differential signal received by the HCPL-2602. TTL data is converted to a differential signal via the differential line driver 9614, and transmitted over twisted-pair wire. The Schottky diode helps to improve the turn-on and turn-off delays.

**Performance of Circuit**

- **Signaling rate**: up to 2 MBd at 90 m (up to 10 MBd with polarity non-reversing driver)
- **Optocoupler common-mode transient rejection**: 10,000 V/μs (typical)

**Benefits**

- Integrated line termination and voltage clamping saves board space
- Differential driver and optical isolated receiver reduce or eliminate transient noise interference

**Alternative Agilent Parts**

1) HCPL-2611 High CMR, High Speed Optocoupler
2) HCPL-0601/0631 Small Outline, High Speed Optocoupler
3) HCNW2601 Widebody, High Speed Optocoupler
**Description**
Profibus (Process Fieldbus) is essentially a twisted wire pair serial link very similar to RS-485 or 422. Profibus speed standard is either lower speed (1.5 MBd) or higher speed (12 MBd). In this application circuit the Profibus is shown to be isolated with HCPL-061N (single channel optoisolator) and HCPL-063N (dual channel optoisolator).

**Performance of Circuit**
- Typical data rate (NRZ): Up to 10 Mbit/s
- Multipoint bus transmission line application
- Open collector output, HCMOS/TTL compatible
- Maximum propagation delay of optoisolator: 0.1 µsec
- Minimum common mode transient immunity: 15 kV/µsec at V_CM = 1000 V
- Low minimum drive current: 3 mA

**Benefits**
- Low input drive current maximizes LED lifetime/reliability
- Speed optimized for Profibus (1.5 MBd) and RS-422 (10 MBd)
- Performance guaranteed over temperature (-40 to 85°C)

**Alternative Agilent Parts**
1) HCPL-0261 Single Channel Optocoupler
2) HCPL-56XX High CMR, Hermetically Sealed Optocoupler
3) HCPL-050L/060L/070L, HCPL-250L/260L/270L
   3.3 V Optocouplers
4) HCPL-053L/063L/073L, HCPL-253L/263L/273L
   3.3 V Optocouplers
Description
Profibus (Process Fieldbus) is essentially a twisted wire pair serial link very similar to RS-485 or 422. Profibus speed standard is either lower speed (1.5 MBd) or higher speed (12 MBd). In this isolated multipoint transmission application circuit, two different optoisolators are utilized (HCPL-0721 and HCPL-061N).

Performance of Circuit
- Typical data rate (NRZ): Up to 12Mbit/s
- Multipoint bus transmission line application
- Compatible with 5 V CMOS and TTL logic gates
- Maximum propagation delay of optoisolator: 0.04 μsec
- Minimum common mode transient immunity: 10 kV/μsec at $V_{CM} = 1000$ V

Benefits
- Low input drive current maximizes LED lifetime/reliability
- Speed optimized for Profibus and RS-485
- Performance guaranteed over temperature (-40 to 85°C)
**Description**
The 6N136 Low-Input Current Optocoupler is used to detect standard telephone ring signals. At the optocoupler output, a 0.1 µF base-collector capacitor provides a large enough Miller-capacitance so that a low-frequency ring signal (20 to 60 Hz) causes the output to remain low when ringing occurs.

**Performance of Circuit**
- Can detect 20 to 60 Hz, 30 to 80 V<sub>RMS</sub> telephone ring signals

**Benefits**
- Simple and inexpensive circuit for ring signal detection
- Meets worldwide regulatory isolation standards

**References**
6N139 Low-Input Current Optocoupler Technical Data

**Alternative Agilent Parts**
1) HCPL-0701 Small Outline, Low-Input Current Optocoupler
2) HCPL-3700/60 Threshold Sensing Optocoupler
3) HCNW139 Low-Input Current Optocoupler
Description
The HCPL-4701 Low Power Optocoupler is suitable for standard telephone line interface functions such as: ring detection, line polarity, and power on/off detection. Integrated Services Digital Network (ISDN) applications severely restrict the input power that an optocoupler interface circuit can use, which makes the HCPL-4701 an ideal choice. Similarly, HCPL-270L, 3.3V optocoupler could be used which is compatible with JEDEC low voltage specifications.

Performance of Optocoupler
- Input current for turn-on: 40 µA
- Typical total power dissipation with \( I_F = 40 \text{ µA} \): < 3 mW
- Typical propagation delay: 65 µs

Benefits
- Low power dissipation
- Compatible with 3V Logic

Introduction
Optoisolators transfer analog and digital signals from one circuit section or module to another in the presence of a large potential difference or induced electrical noise between the ground or common points of these modules. Examples of analog isolation applications are interfaces to A/D converters, sensing circuits such as thermocouples and transducers, patient monitoring equipment, motor speed and position measurement circuits, audio and video amplifiers, and power supply feedback.

Basic Building Blocks for Analog Isolation
Agilent Technologies’ HCNR200/1 and HCPL4562 constitute basic optical coupling building blocks for high linearity isolation applications. Figures 1 and 2 show the respective optical coupling mechanisms for these two optoisolators. Both these isolators use high-performance AlGaAs LEDs and photodiode combinations with higher speed and linearity compared to conventional optoisolators. The HCNR200/1 LED illuminates two closely matched photodiodes, one on the input side, and another on the output side. With a suitable applications circuit for the HCNR200/1, the nonlinearity and drift characteristics of the LED can be virtually eliminated. The output photodiode produces a photocurrent that is linearly related to the light output of the LED. The close matching of the photodiodes and advanced design of the package ensure the high linearity and stable gain characteristics of the optoisolator.

The HCNR200/1 optoisolator can be used as a basic analog isolation building block for a wide variety of applications that require good stability, linearity, bandwidth and low cost. The HCNR200/1 is very flexible and, by appropriate design of the application circuit, is capable of operating in many different modes, including unipolar, bipolar, ac/dc, inverting and non-inverting.

The HCPL-4562 and HCNW4562 are recommended for very high bandwidth (up to 15 MHz) AC analog designs. If the output transistor is biased in the active region, the current transfer ratio relationship for the HCPL-4562 can be represented as:

$$I_C = K \left( \frac{I_F}{I_{FQ}} \right)^n$$

where $I_C$ is the collector current; $I_F$ is the LED input current, $I_{FQ}$ is LED input current at which $K$ is measured; $K$ is the collector current when $I_F = I_{FQ}$; and $n$ is the slope of $I_C$ vs. $I_F$ on logarithmic scale.

The exponent $n$ varies with $I_F$, but over some limited range of $DI_F$, $n$ can be regarded as a constant. For ac-signal applications, the HCPL-4562 can be biased at an appropriate quiescent current where the ratio of the incremental photodiode current to incremental LED current is nearly constant. Figure 3 shows the linearity characteristics of the HCPL-4562.

Figure 1. HCNR-200/1 High Linearity Analog Isolator
Figure 2. HCPL-4562 High Bandwidth Analog Isolator
Figure 3. HCPL-4562 Base Photo Current vs. Input Current
ANALOG APPLICATIONS
High Speed Isolation Amplifier

Description
This is a high-speed, low-cost isolation amplifier for use in the feedback path of switch-mode power supplies or motor speed and position measurement. This circuit can be used in applications where high bandwidth, low-cost, and stable gain are required, but where accuracy is not critical.

Performance of Optocoupler
• 1.5 MHz bandwidth
• Stable gain
• Low-cost support circuit
• Circuit couples only positive voltage signals

Benefits
• Low cost solution for coupling positive voltage analog signals
• Simple way for sending power supply voltage feedback signal across isolation barrier

References
HCNR200/1 Technical Data

Alternative Agilent Parts
1) HCPL-7800A, HCPL-7800, HCPL-7840 Isolation Amplifier
2) HCPL-4562 Wideband Analog/Video Optocoupler
3) HCPL-785X Hermetically Sealed Isolation Amplifier
ANALOG APPLICATIONS
Precision Isolation Amplifier for Unipolar Signals

Description
This circuit uses the HCNR200/1 High-Linearity Analog Optocoupler to achieve high accuracy and wide dynamic range at a reasonable cost. This is accomplished by using low-cost, precision op-amps with very low input bias currents and offset voltages. The circuit couples only positive voltage analog signals.

Performance of Circuit
- DC to 10 kHz bandwidth
- Stable gain
- 0.1% nonlinearity
- 1 mV to 10 V input/output voltage range

Benefits
- Low-cost, high-accuracy solution for coupling analog signals
- Easy availability of support circuit components
- No offset adjustment is required

3) HCPL-785X Hermetically Sealed Isolation Amplifier
ANALOG APPLICATIONS
Isolation Amplifier for Bipolar Signals - Circuit No. 1

Description
This circuit shows how the HCNR200 High Linearity Optocoupler can be used for transmitting bipolar analog signals across an isolation boundary. This circuit uses two optocouplers: OC1 and OC2; OC1 handles the positive portions of the input signal and OC2 handles the negative portions. Diodes D1 and D2 help reduce cross-over distortion by keeping both amplifiers active during both positive and negative portions of the input signal.

Performance of Circuit
- 0.01% nonlinearity
- Bandwidth: dc to 100 Hz
- Low transfer gain variation: ±5% (K3 of HCNR201)

Benefits
- Low drift
- Low crossover distortion within the dc to 100 Hz frequency band
- Good linearity
- Very low offset

References
HCNR200/1 Technical Data

Alternative Agilent Parts
1) HCPL-7800A, HCPL-7800, HCPL-7840 Isolation Amplifier
2) HCPL-785X Hermetically Sealed Isolation Amplifier
Description
This circuit shows how bipolar analog signals can be transmitted across an isolation boundary by using just one HCNR200 optocoupler. This circuit provides an easy interface to A/D converters with two output signals: an analog signal proportional to the magnitude of the input signal, and a digital signal corresponding to the Sign of the input signal. The HCNW138 optocoupler, which couples the Sign signal, can be substituted with a faster optocoupler in case the Sign changes faster than 50 kHz.

Performance of Optocoupler
- 0.01% nonlinearity
- Wide bandwidth: dc to 1 MHz
- Low transfer gain variation: ±5% (K3 of HCNR201)

Benefits
- Low drift
- Very low offset

3) HCPL-785X Hermetically Sealed Isolation Amplifier
### Description

This circuit with the HCPL-4562 Wideband Analog/Video Optocoupler functions as an ac-coupled isolation amplifier that can be used for coupling audio or video signals. The input circuit biases the optocoupler LED at a quiescent current of about 6 mA, determined primarily by resistors R1, R2, and R3. Diode D1 helps to stabilize the operating point over the operating temperature range. An ac-coupled signal will modulate the collector current of transistor Q1 and the optocoupler LED. The output circuit consists of a simple transresistance (current-in, voltage-out) amplifier followed by a common-emitter amplifier stage.

### Performance of Circuit

- Typical bandwidth: 13 MHz
- Nominal gain of circuit: 1
- Isolation-mode rejection: 46 dB at 1 kHz
- Overall nonlinearity: 0.5%
- Optocoupler input current range: 4 mA-8 mA

### Benefits

- Simple solution for coupling audio and video signals

Isolated Video Interface

Description
This circuit, with the HCPL-4562 Wideband Analog/Video Optocoupler, is optimized for video signal coupling. The peaked response of the detector circuit helps extend the frequency range over which the gain is relatively constant. The number of gain stages, the overall circuit topology, and the dc bias points are all chosen to maximize the bandwidth.

Performance of Circuit
• Typical bandwidth: 15 MHz
• Typical Gain variation: -1.1 dB at 5 MHz with reference at 0.1 MHz
• Isolation Mode Rejection: 122 dB at 120 Hz

Benefits
• Cost-effective, high performance video interface circuit

Inverter Design Using Gate Drive and Current Sense Optocouplers

**System Overview**
A typical motor drive and power control system shown in Figure 1 requires isolation between the high voltage devices (IGBT/MOSFET) and the low voltage devices (microcontroller). In addition to meeting the severe requirements for the isolation function, Agilent Technologies optocouplers provide customized functionality such as direct gate drive for IGBTs or power MOSFETs, and analog isolation for motor current sensing, voltage sensing, speed measurement, and position measurement.

**Isolated Gate Drive and IPM Interface**
Many motor drive and power control systems use pulse width modulation switching of power devices to generate a three phase variable voltage and variable frequency power source. High performance motor drives require precision timing for turning on and turning off the power devices on the inverter. The microcontroller that controls the turn-on and turn-off of these power devices needs to be isolated from the high voltage inverter side. Agilent Technologies offers a variety of optocouplers that have built-in gate drive capability. For solutions that require only a simple isolation interface, Agilent provides Intelligent Power Module (IPM) interface optocouplers. All of Agilent’s gate drive and IPM interface optocouplers meet stringent industrial requirements with critical performance:
- Minimum Common Mode Rejection: 10 kV/µs slew rate at 1,500 V peak transients
- Wide Operating Temperature Range: -40°C to +85°C
- Over Current Protection and Fault Feedback (HCPL-316J)
- Safety Standards Certifications: UL, CSA, VDE
- Fast Switching Speeds: 500 ns range (see detailed part number specifications)
- Wide Supply Voltage Range: 15 V to 30 V

MOTOR CONTROL APPLICATIONS

Isolated Current and Voltage Sensing
Agilent Technologies provides several analog isolation amplifier products for isolated precision current and voltage sensing for monitoring motor performance. Agilent also offers a digital output isolation amplifier for direct connection to a microcontroller. Compared to Hall-Effect sensors, Agilent’s isolation amplifiers have excellent gain and offset characteristics, especially very low offset drift over a wide temperature range. In addition, they provide a compact, low-cost, and reliable solution for motor drive designers that need to accurately measure motor voltage and current. Some of the key performance features include:
• 12-bit linearity (HCPL-7860)
• over current detection (HCPL-788J)
• ±200 mV input range
• -40°C to +85°C operating temperature range
• 15 kV/µs isolation transient immunity
• Safety Standards Certifications: UL, CSA, VDE

Analog Signal Isolation for Speed and Position Measurement
Agilent Technologies offers a low cost, high accuracy, isolated amplifier solution for the measurement of speed and position in a motor. With the use of Agilent Technologies’ HCNR201 and low cost operational amplifiers, circuit designers have the flexibility of designing analog isolation amplifiers that have low input bias currents, high bandwidth, stable gain, and very high linearity.

Common Mode Rejection
The detector shield in the optocoupler prevents CMR failure due to capacitive coupling from the input side of the optocoupler, through the package, to the detector IC. However, this shield does not eliminate the capacitive coupling between the LED and the optocoupler output pins and output ground as shown in Figure 2. This capacitive coupling causes perturbations in the LED current during common mode transients and becomes the major source of CMR failures for a shielded optocoupler. The main design objective of a high CMR LED drive circuit becomes keeping the LED in the proper state (on or off) during common mode transients. The recommended application circuits for Agilent’s gate drive applications can achieve 15 kV/µs CMR while minimizing component complexity.

IPM Dead Time and Propagation Delay Specifications
Many of Agilent’s gate drive and IPM interface optocouplers include a Propagation Delay Difference (PDD) specification intended to help designers minimize “dead time” in their power inverter designs. Dead time is the time periods during which both the high and low side power transistors (Q1 and Q2) of a power module are off. Any overlap in Q1 and Q2 conduction will result in large currents flowing through the power devices between the high and low voltage motor rails.

To minimize dead time the designer must consider the propagation delay characteristics of the optocoupler as well as the characteristics of the IGBT gate drive circuit. Considering only the delay characteristics of the optocoupler (the characteristics of the IGBT gate drive circuit can be analyzed in the same way) it is important to know the minimum and maximum turn-on (tPHL) and turn-off (tPLH) propagation delay specifications, preferably over the desired operating temperature range.

Figure 2 AC Equivalent for a Digital Optocoupler
Another cause of CMR failure for a shielded optocoupler is direct coupling to the optocoupler output pins through CLED01 and CLED02 in Figure 2. Many factors influence the effect and magnitude of the direct coupling including: the use of an internal or external output pull-up resistor, the position of the LED current setting resistor, the connection of the unused input package pins, and the value of the capacitor at the optocoupler output (CL). The recommended gate drive and IPM interface application circuits for Agilent optocouplers have been optimized to reduce the likelihood of CMR failure.
The limiting case of zero dead time occurs when the input to Q1 turns off at the same time that the input to Q2 turns on. This case determines the minimum delay between LED1 turn-off and LED2 turn-on, which is related to the worst case optocoupler propagation delay waveforms, as shown in Figure 3. A minimum dead time of zero is achieved in Figure 3 when the signal to turn on LED2 is delayed by \((t_{PLH max} - t_{PHL min})\) from the LED1 turn off. Note that the propagation delays used to calculate PDD are taken at equal temperatures since the optocouplers under consideration are typically mounted in close proximity to each other. (Specifically, \(t_{PLH max}\) and \(t_{PHL min}\) in the Figure 3 equations are not the same as the \(t_{PLH max}\) and \(t_{PHL min}\) over the full operating temperature range, specified in the data sheet). This delay is the maximum value for the propagation delay difference specification that is specified at 450 ns for the HCPL-4506 over an operating temperature range of -40°C to +100°C. Delaying the LED signal by the maximum propagation delay difference ensures that the minimum dead time is zero, but it does not tell a designer what the maximum dead time will be. The maximum dead time occurs in the highly unlikely case where one optocoupler with the fastest \(t_{PLH}\) and another with the slowest \(t_{PHL}\) are in the same inverter leg. The maximum dead time in this case becomes the sum of the spread in the \(t_{PLH}\) and \(t_{PHL}\) propagation delays as shown in Figure 3.

The maximum dead time is also equivalent to the difference between the maximum and minimum propagation delay difference specifications. The maximum dead time (due to the optocouplers) for the HCPL-4506 is 600 ns over an operating temperature range of -40°C to +100°C.

Figure 3. Propagation Delay and Dead Time

MAXIMUM DEAD TIME (DUE TO OPTOCOUPLER)
= \((t_{PLH max} - t_{PHL min})\) + \((t_{PHL max} - t_{PLH min})\)
= \((t_{PHL max} - t_{PHL min})\) + \((t_{PLH min} - t_{PLH max})\)
= \(PDD^*\) MAX. - \(PDD^*\) MIN.

PROPAGATION DELAY DIFFERENCE (PDD) MAX.
= \((t_{PLH} - t_{PHL})\) MAX.

NOTE: THE PROPAGATION DELAYS USED TO CALCULATE THE PDD AND MAXIMUM DEAD TIME ARE TAKEN AT EQUAL TEMPERATURES.
Bootstrap Power Supply Circuit for Power Control Systems

Figure 4 shows a bootstrapped output power supply circuit that has the following benefits:

- eliminates the need for an isolated power supply or a dc-to-dc converter,
- lower cost solution compared to transformer based power supply,
- less printed circuit board space.

This circuit includes a bootstrap circuit for providing output power to the HCPL-316J gate drive optocouplers, thereby eliminating the need for isolated power supplies or dc-to-dc converters. It can be modified to suit other Agilent gate drive optocouplers and current/voltage sensing isolation amplifiers.

Component values were chosen for a 350 V rail = HV+ - HV- (240 V x 1.414). When the lower IGBT is turned on, V_{C1H} charges up (through D_{1H}) to a voltage of:

\[ V_{C1H} = HV+ - [HV+ + V_{SATM2} + V_{CC2H} + V_F(D_{1H})] \]
\[ = 350 V - 3 V - 18 V - 1 V \]
\[ = 328 V \]
where $V_{\text{SATM2}}$ is the saturation or “on” voltage across the collector-emitter of IGBT M2; $V_{F(D1H)}$ is the voltage across diode D1H; and HV+, HV- are the rail voltages.

When M2 (low IGBT) switches off and M1 (upper IGBT) switches on, $V_{E(H)}$ pulls up to HV+ - $V_{\text{SATM1}}$. This causes $C_{4H}$ to become charged through D2H. Charge sharing between $C_{1H}$ and $C_{4H}$ results in the voltage across $C_{4H}$ which (in the absence of clamping diode DZ2H) can be approximated by:

$$C_{4H} \times \Delta V_{C4H} = C_{1H} \times 328 \text{ V}$$

$$\Rightarrow \Delta V_{C4H} = 19.6 \text{ V}$$

where $\Delta V_{C4H}$ is the voltage drop across $C_{4H}$. The negative gate bias then is held at 12 V by clamping Zener DZ2H.

Shunt Resistor Selection for Current Sensing

The current-sensing shunt resistor should have low resistance to minimize power dissipation, low inductance to minimize di/dt induced voltage spikes which could adversely affect operation, and reasonable tolerance to maintain overall circuit accuracy. Choosing a particular value for the shunt is usually a compromise between minimizing power dissipation and maximizing accuracy. Smaller shunt resistance decreases power dissipation, while larger shunt resistance can improve circuit accuracy by utilizing the full input range of the isolated modulator.

Agilent Technologies recommends Dale Electronics’ two-terminal shunt resistors for low cost applications. These resistors are suitable for measuring current up to 28 Amperes. See comparison table below.

Several four-terminal shunts from Isotek suitable for sensing currents in motor drives up to 71 Amperes (71 hp or 53 kW) are shown in the comparison table below; the maximum current and motor power range for each of the PBV-series shunts are indicated. For shunt resistance from 50 mW down to 10 mW, the maximum current is limited by the input voltage range of the isolated modulator. For the 5 mW and 2 mW shunts, a heatsink may be required due to the increased power dissipation at higher currents.

**Description**  
The HCPL-3120 drives the IGBTs or MOSFETs directly in this circuit and provides full regulatory approved isolation between the power and control circuits. The output power supply can be derived from rail to rail supply by using a bootstrap circuit illustrated in the “Inverter Design using Gate Drive and Current Sense Optocoupler” section. The value of Rg in the above circuit is chosen to control the peak gate charge and discharge current as well as the output power dissipation.

**Performance of Circuit**  
- Peak output current of 2.0A improves driving efficiency.
- Superior common mode transient noise immunity: 15 kV/µs@Vcm = 1500 V.
- Low Icc current and wide Vcc range: 15 V - 30 V over -40°C to 100°C.
- Low Vcc of 0.5 V eliminates the need for negative Supply Voltage (Vee).
- World wide regulatory approval.
- Fast under voltage lockout response: 0.6µs.

**Alternative Agilent Parts**

5) HCPL-316J 2.0 Amp Isolated Gate Driver with Integrated Desaturation Detection and Feedback.
MOTOR CONTROL APPLICATIONS
Dual Channel Isolated Integrated Gate Driver for IGBT/MOSFET

**Description**
The HCPL-314J drives 2 IGBTs or MOSFETs directly in this circuit and provides full regulatory approved isolation between the power and control circuits. The output power supply can be derived from rail to rail supply by using a bootstrap circuit illustrated in the “Inverter Design using Gate Drive and Current Sense Optocoupler” section. The value of Rg in the above circuit is chosen to control the peak gate charge and discharge current as well as the output power dissipation.

**Performance of Circuit**
- Dual in 1 package saves assembly costs.
- Peak output current of 0.4 A best suited for low and medium power IGBTs.
- Superior common mode transient noise immunity: 10 kV/µs@Vcm = 1500 V.
- Low Icc current and wide Vcc range: 10 V - 30 V over -40°C to 100°C.
- Low V<sub>OL</sub> of 1V eliminates the need for negative supply voltage (Vee).
- Worldwide regulatory approval.

MOTOR CONTROL APPLICATIONS
Isolated Gate Drive for IGBT/MOSFET with Integrated
Desaturation Protection and Fault Feedback

Description
The HCPL-316J drives IGBTs or MOSFETs directly and provides additional IGBT desaturation
protection. The Vce of the IGBT is monitored by Desat pin and the IGBT will be slowly turned off
if Vdesat exceeds a threshold of 7 V. A fault feedback signal is propagated to the input side to
notify the micro-controller of the detected fault condition. This FAULT output remains low until
the part is reset. The 0.1 pF blanking capacitor shown in the diagram above will delay the rise
of VDesat for a period of around 4 µs to allow the IGBT sufficient time to turn on and the collector
to settle to a low VDesat.

Performance of Circuit
• Gate Drive Current : 2.0 A
• Common mode Transient Rejection: 15 kV/µs@VCM = 1.5 kV
• IGBT gate protection response time: 3 µs.
• IGBT fault signal propagation delay: 10 µs.

Benefits:
• Reduced assembly costs
• CMOS/TTL compatible
• Local IGBT soft shutdown
• Worldwide regulatory approval

5) HCPL-3120 2.0 Amp Isolated Gate Driver.
MOTOR CONTROL APPLICATIONS
Isolated Interface for Intelligent Power Module Gate Drive

Description
The HCPL-4506 provides isolation between the controller and the IPM (Intelligent Power Module). This optoisolator provides world-wide safety certification (UL, CSA, VDE, BSI). The HCPL-4506 optocouplers can reject common mode transients that have slew rates as high as 15 kV/µs and peak voltage up to 1500 V. Furthermore, this optocoupler has guaranteed Pulse Width Distortion and Propagation Delay Difference specifications that allow the circuit designer to reduce switching dead time and improve inverter efficiency.

Performance of Optocoupler
- Minimum 15 kV/µs transient immunity
- Maximum propagation delay: 500 ns
- Maximum propagation delay difference between any two HCPL-4506s: 450 ns
- Specification guaranteed over -40°C to 100°C operating temperature range.

Benefits
- World wide regulatory approval.
- Reduced deadtime

Alternative Agilent Parts
1) HCNW4506 widebody, V_{FORM}=1414 V, HCPL-J456, V_{FORM}=891 V, HCPL-0456, SO8 package.

3) HCPL-4503, HCNW4503, HCPL-0453.
MOTOR CONTROL APPLICATIONS
Low Cost Isolated Phase Current Sensing with Analog Output

Description
The HCPL-7840 Isolation Amplifier can be used for isolating the motor current sensing element from the control circuit while at the same time transmitting precision analog signals. This circuit requires a low cost shunt resistor for monitoring the motor current. The voltage across the sensing resistor is fed to the HCPL-7840 input pins 2 and 3. A floating power supply (which in many applications could be the same one used to drive the high side power transistors) is regulated to 5 V using a simple three-terminal voltage regulator, 78L05. The differential output from the HCPL-7840 isolation amplifier is converted to a ground-referenced single-ended output voltage with a simple differential amplifier circuit (MC34082A and associated components).

Performance of Circuit
- Sense current: Up to 200 A
- Optocoupler bandwidth: Up to 100 kHz
- Optocoupler nonlinearity: 0.2%
- Optocoupler input offset voltage: 0.2 mV (typical)
- Optocoupler common-mode rejection: 15 kV/µs

Benefits
- Small size and lower profile circuit compared to Hall-Effect device current sensing circuits.
- Industry standard low profile components are used in this circuit.
- High precision measurement while maintaining common mode transient immunity.

Alternative Agilent Parts
1) HCPL-7800A: 1% part-to-part gain tolerance, HCPL-7800: 3% part-to-part gain tolerance.
2) HCPL-788J: single ended output isolation amplifier with integrated over current detection.
MOTOR CONTROL APPLICATIONS
Isolated A/D Converter for Phase Current Sensing

Description
The HCPL-7860 Isolated Modulator and the HCPL-x870 Digital Interface IC together form an isolated programmable two-chip analog-to-digital converter. The isolated modulator allows direct measurement of motor phase currents in power inverters while the digital interface IC can be programmed to optimize the conversion speed and resolution.

Performance of Circuit
- Resolution due to linearity: 12 bits at \( t_{\text{DELAY}} = 18 \mu s \), 14 bits at \( t_{\text{DELAY}} = 94 \mu s \)
- Common-mode transient rejection: \( \frac{dV}{dt} = 15 \text{kV/\mu s} \) @ \( V_{\text{CM}} = 1500 \text{V} \)
- Signal-to-Noise: SNR = 62 dB (minimum)
- Regulatory Isolation Ratings: \( V_{\text{ISO}} = 3750 \text{V} \) (per UL 1577), \( V_{\text{IDM}} = 848 \text{V} \), \( V_{\text{IOTM}} = 6000 \text{V} \)
- Input Offset Drift: \( 4 \mu \text{V/°C} \) (typical)
- Reference Voltage Tolerance: \( \pm 4\% \) (\( \pm 1\% \) within shipment tube)

Benefits
- Integrated analog-to-digital converter means fewer components required.
- High common-mode transient rejection ensures no corruption of data.
- Low gain temperature-coefficient and offset voltage ensure high accuracy measurements.

MOTOR CONTROL APPLICATIONS
Low Cost Isolated Phase Current Sensing with Analog Output and Over Current Detection

Description
The HCPL-788J can be used for isolating the motor current sensing element from the control circuit while at the same time transmitting precision analog signals and over current fault signal. This circuit requires a high precision-sensing resistor for monitoring the motor current. The voltage across the sensing resistor is fed to the HCPL-788J input pins 2 and 3. The single-ended output allows it to interface directly with the A/D port of the micro-controller. The sensing resistor is available from several suppliers, which are listed in the “Inverter Design using Gate Drive and Current Sense Optocoupler” section.

Performance of Circuit
- Overcurrent fault response: 3 \( \mu \)s typical
- Sense current up to 100 A or more
- Bandwidth: 30 kHz typical
- Nonlinearity: 0.06% typical
- Input offset voltage: 3 mV max. over temp.
- Common-mode rejection: 10 kV/\( \mu \)s@\( V_{CM} = 15 \) kV min.

Benefits
- No additional fault detection circuitry needed
- Direct interface with micro-controller
- Smaller size and lower profile compared to Hall-Effect device based current sensing circuits
- High precision measurement while at the same time maintaining transient immunity
MOTOR CONTROL APPLICATIONS
Isolated Inverter Rail Voltage Sensing using an Isolation Amplifier

Description
The HCPL-7840 isolation amplifier can be used for sensing the rectified dc power supply voltage in a power inverter. An isolated 5 V power supply regulated to 5 V using a simple three-terminal voltage regulator powers the HCPL-7840 input circuit. The resistor divider network is used so that the full scale voltage at the HCPL-7840 input is 200 mV. The impedance of the resistor divider must be less than 1 kΩ so that the input resistance (500 kΩ) and input bias current (1 mA) of the isolation amplifier do not affect the accuracy of the measurement. To obtain higher bandwidths, the input bypass capacitor (across HCPL-7840’s pins 2 and 3) can be reduced, but it should not be reduced much below 1000 pF to maintain gain accuracy of the isolation amplifier.

Performance of Circuit
• 15 kV/µs transient rejection
• 0.05% nonlinearity
• 5% gain tolerance

Benefits
• Few components
• High electrical noise immunity

2) High precision current sensing resistor suppliers: Dale in USA; Isabellenhutte in Germany; and PCN in Japan
The HCPL-4562 Linear Optocoupler is used in a servo circuit to sense the rectified dc power supply voltage of a power inverter. The series resistor $R_1$ limits the current that drives the input LED of optocoupler $U_1$. The forward current through the LED of the HCPL-4562 optocoupler is proportional to the dc high voltage power supply rail.

When the circuit is balanced with the potentiometer $R_3$, the output voltage $V_O$ is proportional to the high voltage dc power supply as shown by the equation:

$$\frac{V_O}{V_I} = \frac{R_2}{R_1}$$

### Performance of Circuit
- 122 dB isolation mode rejection ratio
- 0.25% nonlinearity
- $\pm0.3^\circ C$ gain variation temperature coefficient

### Benefits
- No isolated 5 V input power supply is required for optocoupler $U_1$
- Simple circuit

### Alternative Agilent Parts
1) HCPL-7800A: 1% part-to-part gain tolerance
2) HCPL-7800: 3% part-to-part gain tolerance
MOTOR CONTROL APPLICATIONS
Low Cost Isolation Amplifier for Motor Speed and Position Measurement

Description
This is a high-speed, low-cost isolation amplifier that can be used for the measurement of motor speed and position. The analog signal coming from the motor is assumed to be 0 to 10 V, or 4 to 20 mA. This circuit can be used in applications where high bandwidth, low-cost, and stable gain are required, but where accuracy is not critical. This circuit is a good example of how a designer can trade off accuracy to achieve improvements in bandwidth and cost. The circuit has a bandwidth of about 1.5 MHz with stable gain characteristics and requires few external components. R1 is selected to achieve an LED current of about 7 - 10 mA at the nominal input operating voltage according to the following equation:

\[ I_F = \frac{V_{IN}}{R1} / K1 \]

where K1 (i.e., \(I_{PD1}/I_F\)) of the optocoupler is typically about 0.5%. R2 is then selected to achieve the desired output voltage according to the equation, \(V_{OUT}/V_{IN} = R2/R1\). The purpose of R4 and R6 is to improve the dynamic response (i.e., stability) of the input and output circuits by lowering the local loop gains. R3 and R5 are selected to provide enough current to drive the bases of Q2 and Q4. And R7 is selected so that Q4 operates at about the same collector current as Q2.

Performance of Circuit
• 1.5 MHz bandwidth
• Stable gain
• Low-cost support circuit
• Circuit couples only positive voltage signals

Benefits
• Low cost solution for coupling positive voltage analog signals
• Simple way for isolating motor speed and position analog signals
Industrial Applications

AC/DC Voltage Threshold Sensing

Description
The HCPL-3700/60 Threshold-Sensing Optocoupler can be used for sensing the ac/dc power on/off condition. At the optocoupler input, only a pair of series resistors $R_x/2$ are required to limit the current. The ac signal can be filtered with a capacitor at either the input or the output of the optocoupler. For more information refer to Agilent Application Note AN 1004, “Threshold Sensing for Industrial Control Systems.” The value of $R_x$ determines the threshold sensing voltage.

Performance of Circuit
- HCPL-3760 optocoupler threshold input current: 1.3 mA (typical)
- Typical optocoupler propagation delay: 10 $\mu$s
- Optocoupler common mode transient immunity: 600 V/$\mu$s (typical)
- Maximum input voltage: up to 1000 Vdc, or 800 Vac

Benefits
- HCPL-3700/60's built-in diode bridge and hysteresis circuit reduces component count
- HCPL-3760's low threshold sensing current reduces power dissipation
- Threshold voltage can be adjusted by external resistor $R_x$

HCPL-576X: Hermetically Sealed Threshold Sensing Optocoupler

Agilent Technologies
**Description**
The HCPL-0708 high-speed, optocoupler isolates the low-voltage logic circuit from the high-voltage Flat-Panel Display row/column drivers. Examples of Flat-Panel Display technologies requiring such high voltage technologies are Electro-Luminescence, Fluorescence, and Plasma technologies. The optocoupler serves the functions of level shifting and safety isolation.

**Performance of Optocoupler**
- Maximum propagation delay time: 60 ns
- Typical pulse width distortion of 15 ns
- Common-mode transient rejection: 15,000 V/µs at 1000 V peak

**Benefits**
- Compact size and easy interface compared to pulse transformers
- Low input current allowing CMOS interface
- Low component count

**Alternative Agilent Parts**
1) HCPL-0201/11 Small Outline Low Input Current Optocoupler
2) HCPL-52XX Hermetically Sealed Low Input Current Optocoupler
3) HCNW-2201/11 Widebody Low Input Current Optocoupler
4) HCPL-2430/1 20 MBd Logic-Gate Optocoupler
Power Supply Applications

Optical Isolation in a Switching Power Supply - Circuit No. 1

Description
Switching power supplies often need to couple digital and analog signals between the primary and secondary circuits. The above schematic shows an analog error signal representing the difference between the output voltage and the reference voltage being fed back to the primary side using a HCNR200/1 Analog Optocoupler. The analog error signal helps the pulse-width modulation (PWM) controller determine the exact pulse-width to make the filtered output voltage match the system reference voltage. In a similar manner, the HCPL-0708 Digital Optocoupler can be used to monitor the primary side power-off and under-voltage condition.

Performance of Optocoupler
• HCNR200/1 has 0.01% non-linearity and up to 1 MHz bandwidth
• HCPL-0708 has 60 ns maximum propagation delay time
• Both HCNR200/1 and HCPL-0708 optocouplers meet worldwide regulatory insulation guidelines

Benefits
• Accurate monitoring and control of secondary output voltage
• Power off condition detectable at an early stage enabling the microprocessor to save critical information

Optical Isolation in a Switching Power Supply -
Circuit No. 2

Description
The above figure shows a push-pull switching power supply that utilizes the HCPL-2200 optocoupler to drive switching transistors. The above circuit uses a silicon unilateral switch (SUS) to bootstrap start the power supply when power is first applied. The inhibit function in the HCPL-2200 optocoupler has been used to good advantage to provide a common-mode conduction interlock function that will not allow both the switching transistors to turn on at the same time.

Performance of Optocoupler
- Maximum propagation delay: 300 ns
- Input turn-on current: 1.6 mA
- Common-mode transient rejection: 1000 V/µs

Benefits
- The power switches are protected from common-mode conduction failures caused by EMI
- Regulation range is increased since no deadtime is required
- Design is tolerant to propagation delay changes due to lot-to-lot component variations

Optical Isolation in a DC/DC Converter

Description
The HCPL-0708 high speed optocoupler provides very good safety isolation between primary and secondary sections of the DC/DC converter as shown in the above figure. The switching frequency specification of the DC/DC converter is met by the low propagation delay (60 ns max.) and 15 ns typical pulse width distortion of HCPL-0708 CMOS compatible high speed optocoupler. The smaller size, better noise immunity performance, high reliability and wide operating temperature make HCPL-0708 ideally suited for such applications.

Performance of Optocoupler
- HCPL-0708: 60 ns maximum propagation delay time and 15 ns typical pulse width distortion
- 10KV/µs minimum CMR @ Vcm =1KV
- Wide operating temperature: -40 to 100°C

Benefits
- Accurate monitoring and control of output voltage
- Low propagation delay
- Small size and high reliability
- CMOS compatible and easy interface
